Raman amplification /'r?:m?n/ is a way of increasing the signal strength in an optical fiber. It is often used in a fiber that carries a signal for a long distance (such as in an undersea cable). Technically, it works by stimulating Raman scattering, in which a lower frequency "signal" photon induces inelastic scattering of a higher-frequency "pump" photon in an optical medium in the nonlinear regime. As a result, another "signal" photon is produced, with the surplus energy resonantly passed to the vibrational states of the ...

Distributed Raman Amplifiers: These amplifiers use the transmission fiber itself as the gain medium. They provide a more uniform gain distribution and can reduce the overall noise figure.

In addition to applications in nonlinear and ultrafast optics, Raman amplification is used in optical telecommunications, allowing all-band wavelength coverage and in-line distributed signal amplification.

Theoretical studies have shown that the distributed Raman Amplifier can be able to achieve a higher optical signal to noise ratio (OSNR) than the discrete amplifier.
